

pivot control

A pivot control provides a quick way to manage views within the application. Pivot controls can be used for filtering large datasets, viewing multiple data sets, switching application views, or related content. The pivot control places them horizontally next to each other, and manages the left/right navigation (flick/pan) of the individual pages. Gesturing left and right on the page advances the pivot experience regardless of what controls are on the page.

The visual structure can also be used in a static manner where multiple views aren't exposed.
